Table 2. The amphorae from the western part of the youngest Augustan fortress (after: Van den Berg *et al.* 2017).

Vilvorders (2015, 240) suggestion is not surprising. They suggest that preserved meat was transported in such pots over long distances from the Condroz to the consumers. This assumption is supported by a pot found on the nearby Kops Plateau containing the bones of 28 preserved song thrushes' briskets (Lauwerier 1993).

Three-quarters of the flagons are made of an orange fabric, only a quarter is white. Flagon Stuart 103/Oberaden 43 (fig. 2.13) is the best represented. In addition, flagons Stuart 133/Oberaden 52 (fig. 2.14), Stuart 131/Oberaden 48-49 (fig. 2.15) and the so-called 'honey pots' Stuart 146 were also common (Niemeijer 2017, 17). The fact that most of the flagons in the Augustan period were made of an orange, slightly sandy fabric is also evident from the finds from the neighbouring Kops Plateau. This is also confirmed by Roth-Rubi's research on flagons of this period, in which she also examined smooth ware from military centres on the banks of the rivers Rhine and Lippe (Roth-Rubi 1979). The amphora sherds give a good picture of the contacts between Nijmegen and other parts of the Roman Empire between 20 and 10 BC. They also show that in this early period the soldiers in the fortress were supplied with olive oil, fish sauce and wine (table 2).

Rare are the Oberaden 21 plates in Pompeian red ware (Niemeijer 2017, 17), which were used to bake or heat food in an oven. On a larger scale, sherds of mortaria with vertical rim Haltern 59 (fig. 5.10)

produced in Lyon and nearby Saint-Romain-en-Gal have been found (Kloosterman 2014b, 199, 201, 203-205). In addition, several fragments of large handmade dolia Stuart 147 with a wheelthrown rim with a black coating (fig. 5.11) have been found. Whether these early dolia came from the löss area between Tienen in Belgium and Cologne in Germany (Borgers 2023, 628) will have to be determined by future research. Furthermore, several sherds of dolia with a small twisted *Wulstrand* were found (fig. 2.19-20), which can be specifically dated to this early period.

From Table 1 (columns 3-7), some conclusions can be deduced about the function of the pottery. Among the tableware, the low proportion of terra sigillata is striking; the tableware is strongly dominated by the fine ware beakers. It can also be concluded that more than half of the pottery comes from small and large containers used for transporting food, wine, fish sauce, olive oil or other goods. The small wheelthrown vessels (cf. figs 2.11, 3.1-6, 5.12-14) are often called cooking pots. Yet, as the fabrics of such pots are often unsuitable for cooking, they are more likely to be containers in which food or other goods were transported (cf. Van Enckevort 2000, 134-135; Collins *et al.* 2009, 193). If the contents were food, some of such pots and their contents were heated in an oven or on a charcoal fire and, when empty, thrown on the rubbish heap, just like modern cans. Other pots were only used for their contents and
